THE IDENTITY AXIS FRAMEWORK

A Geometric Model of Cancer — One-Page Summary

Eric Robert Lawson · OrganismCore (Independent Research) · ORCID: 0009-0002-0414-6544 · OrganismCore@proton.me · 2026-03-07

Cancer is a cell displaced from its normal attractor in the Waddington epigenetic landscape and trapped in a false one. The geometry of that displacement is measurable. The drug target is derivable from the cell of origin — before any literature is consulted. Demonstrated across 41 cancer types with zero structural contradictions.

The Theorem

Every cancer has a measurable axis between:

A **Identity Anchor** — the gene defining what the cell of origin *is*.

H **Convergence Hub** — the gene defining what the cancer has *committed to*.

$R = A/H$ is a continuous, IHC-measurable coordinate in the Waddington landscape. R predicts overall survival. **H is the drug target.**

DOI: 10.5281/zenodo.18898788

The Evidence

Cancer types analysed	**41**
Structural contradictions	**0**
FDA drugs confirming geometry-H	**5**
Phase 1–3 drugs confirming H	**14**
BRCA datasets validated	**7**
BRCA patients validated	**∼7,500**
Novel predictions pre-registered	**14**

The Generative Proof

Five geometric coordinates were *constructed* without starting from any known cancer. Five cancers were derived and confirmed with exactly the predicted properties. **The cancer was the output. The geometry was the input.** This eliminates the pattern-matching objection. Cancer is calculable.

Selected Cancer Axes

Cancer	A	H
Breast	FOXA1	EZH2
ccRCC	GOT1	RUNX1
AML	CEBPA	HOXA9
SCLC-Y	ASCL1	REST
DIPG†	OLIG2	H3K27M
Uveal mel.‡	MITF	BAP1
Ewing	RUNX2/SOX9	EZH2
Thymoma/TC	FOXN1	EZH2
Merkel cell	ATOH1	EZH2
Angiosarcoma	ERG	EZH2

H = EZH2 in 26/41 (72%) of cancers. In the remaining 28%, the framework identifies the specific Polycomb arm operative in that lineage.

†Mirror case: EZH2 paralysed by H3K27M. Tazemetostat contraindicated.

‡PRC1 arm operative. BAP1 loss = attractor deepening.

The FOXA1/EZH2 Clinical Translation — One Step Remaining

Exists	Needed
7 validated datasets	IHC cut-points
∼7,500 patients	300–400 FFPE cases
Survival HR confirmed	PAM50 ground truth
Protocol published	One pathology partner
Cost: $50–$100/pt	H-score scoring

The calibration study translates a computationally validated classifier into a $50 breast cancer subtype tool deployable in any pathology laboratory globally — on standard FFPE tissue, no RNA, no proprietary platform, no capital equipment.

1.2–1.5 million patients per year currently receive no molecular subtype information. This test reaches all of them.

The first institution to run the calibration study is first co-author on the publication.

The geometry came first. The data confirmed it. The drugs follow from the geometry. The patients are the reason for all of it.
